

Package ‘mappings’

May 8, 2026

Type Package
Version 0.2.0
Date 2026-10-23
Title Functions for Transforming Categorical Variables
URL <https://github.com/benjaminrich/mappings>
BugReports <https://github.com/benjaminrich/mappings/issues>
Description Easily create functions to map between different sets of values,
such as for re-labeling categorical variables.
License GPL-3
Suggests testthat
Language en-US
Encoding UTF-8
RoxygenNote 7.3.3
NeedsCompilation no

`as.data.frame.mapping` *Convert a mapping to data.frame*

Description

The resulting `data.frame` has 2 columns: `mapsfrom`, and `mapsto`.

Usage

```
## S3 method for class 'mapping'
as.data.frame(x, ...)
```

Arguments

`x` A [mapping](#).
`...` Ignored.

Value

A `data.frame`.

`cf` *Construct a factor from one or more vectors*

Description

A factor is constructed from one or more atomic vectors. If more than one atomic vector is supplied, then a compound value is constructed by concatenating the values together. The order of the levels is the natural order in which the values appear.

Usage

```
cf(x, ..., sep = ";")
```

Arguments

`x` An atomic vector.
`...` Additional atomic vectors (optional).
`sep` A character to use as a separator when forming a compound value (default `','`).

Value

A factor.

Examples

```
x <- c("A", "B", "A")
y <- c(2, 5, 7)
cf(x, y)
mapping(cf(x, y), c("X", "Y", "Z"))
```

cut_mapping	<i>Mapping from continuous to categorical</i>
-------------	---

Description

Mapping from continuous to categorical

Usage

```
cut_mapping(..., to = NULL, na = NA, ch.as.fact = TRUE)
```

Arguments

...	Passed to <code>cut()</code> .
to	Passed to <code>mapping()</code> .
na	Passed to <code>mapping()</code> .
ch.as.fact	Passed to <code>mapping()</code> .

Value

A function that cuts a numeric vector and maps the result.

Examples

```
x <- c(0, 10, 20, 30, Inf)
m <- cut_mapping(x, right=FALSE,
  to=c("0 to <10", "10 to <20", "20 to <30", ">= 30"))
print(m)
m(c(5, 27, 3, 10, 99))
```

domain	<i>Domain and codomain of a mapping.</i>
--------	--

Description

Domain and codomain of a mapping.

Usage

```
domain(x)
```

```
codomain(x)
```

Arguments

x A [mapping](#).

Value

x A vector of the same type as we supplied when the [mapping](#) was created.

Note

These aren't the true domain and codomain in the mathematical sense; both can contain duplicates.

Examples

```
sex.mapping <- mapping(c("Female", "F", "Male", "M"), c(0, 0, 1, 1))
domain(sex.mapping)
codomain(sex.mapping)
```

inverse	<i>Inverse of a mapping</i>
---------	-----------------------------

Description

Given a [mapping](#) x, return the inverse mapping.

Usage

```
inverse(x)
```

Arguments

x A [mapping](#).

Value

The inverse [mapping](#).

Examples

```
sex.mapping <- mapping(c("Female", "F", "Male", "M"), c(0, 0, 1, 1))
sex.inverse.mapping <- inverse(sex.mapping)
sex.inverse.mapping(c(0, 0, 1, 0))
```

mapping

*Generate a Mapping Function***Description**

This function returns a function that does a simple mapping from one set of value to another. It is a function-generating function.

Usage

```
mapping(from, to, na = NA, ch.as.fact = TRUE, unmapped = NA)
```

```
pmapping(..., unmapped = I)
```

Arguments

from	A vector. This is the domain of the function.
to	A vector of the same length as from. If omitted, then the names of from are taken as the domain, and the values as the values to map to. If from has no names, then to is equal to from (useful for re-ordering factor levels).
na	An alternative way to specify the value that NA maps to. Ignored if from contains NA.
ch.as.fact	A logical. Should the mapping return a factor instead of character?
unmapped	This is a fallback for the case when a value can't be mapped because it doesn't match any of the elements in from. It can either be a single atomic value, or a function that gets applied (which could even be another mapping). Note that this doesn't have any effect on the inverse mapping (which is always based solely on from and to). Default is NA.
...	Passed to mapping().

Details

This function returns a function. When called with a vector argument *x*, this function will return a vector *y* of the same length as *x* and such that each element *y*[*i*] is equal to *to*[*j*] where *j* is the smallest integer such that *from*[*j*] == *x*[*i*], and the value *unmapped* (or, if it's a function, *unmapped*(*x*[*i*])) if no such *j* exists.

`pmapping()` creates a **partial mapping**, which maps certain elements while *preserving* the rest (by making unmapped=I the default).

Note: from will always be matched as a string, even if it is numeric. So, `mapping(1, "A")` and `mapping("1", "A")` are the same, and both functions will return "A" when called with either 1 or "1".

Value

A function that translates from from to to. The function also has an `inverse` which is a function that performs the inverse mapping.

Examples

```
sex.mapping <- mapping(c("Female", "F", "Male", "M"), c(0, 0, 1, 1))
sex.mapping(c("Female", "Female", "Male", "F"))
```

```
sex.mapping <- mapping(0:1, c("Female", "Male"), na="Unknown")
sex.mapping(c(0, 1, NA, 0, 1, 1, 0))
inverse(sex.mapping)(c("Female", "Male", "Unknown"))
```

```
from <- c(0, 1, NA)
to <- c(NA, "Male", "Female")
x <- c(0, 1, NA, 0, 1, 1, 0)
sex.mapping <- mapping(c(0, 1, NA), c(NA, "Male", "Female"))
sex.mapping
sex.mapping(c(0, 1, NA, 0, 1, 1, 0))
inverse(sex.mapping)
inverse(sex.mapping)(c("Female", "Male", NA))
```

```
race.mapping <- mapping(c(
  "1"="WHITE",
  "2"="BLACK OR AFRICAN AMERICAN",
  "5"="AMERICAN INDIAN OR ALASKA NATIVE"))
race.mapping(1:5)
```

```
# Use of `unmapped`
dv.mapping <- mapping("BQL", -99, unmapped=as.numeric)
dv.mapping(c("3.1", "BQL", "2.7", "100"))
```

```
# Map certain elements and preserves the rest
x <- LETTERS[1:5]
pmapping("B", "Z")(x)
mapping("B", "Z", unmapped=I)(x) # Same
```

paste_mapping	<i>A mapping that adds a prefix and/or suffix</i>
---------------	---

Description

A mapping that adds a prefix and/or suffix

Usage

```
paste_mapping(prefix = NULL, suffix = NULL)
```

Arguments

prefix, suffix Character strings.

Value

A mapping function.

Examples

```
# The objective is to turn a numeric vector into a factor such that
# the levels preserve the numeric order but contain the suffix "mg"
# (i.e., so that 2 becomes "2 mg" for instance)
x <- c(1, 2, 1, 10, 3, 2, 2, 1)

# The following does not produce the levels in the desired numeric order
# (because alphabetical ordering places "10" before "2")
factor(paste(x, "mg"))

# The following works, but takes 2 lines of code and requires a variable
# assignment
y <- factor(x)
levels(y) <- paste(levels(y), "mg")
y

# This does the same thing with one line of code and no assignment
paste_mapping(", " mg")(x)

# ----

# In this example, you start with a factor, and want to preserve its ordering
x <- factor(c("Treatment", "Placebo"), levels=c("Treatment", "Placebo"))

# Again, this won't work as desired
factor(paste("Randomized to", x, "Group"))

# But this will
paste_mapping("Randomized to ", " Group")(x)
```

print.mapping	<i>Print a mapping</i>
---------------	------------------------

Description

Print a mapping

Usage

```
## S3 method for class 'mapping'  
print(x, ...)
```

Arguments

x	mapping.
...	Ignored.

Value

Returns x invisibly.

remap	<i>Re-map a variable</i>
-------	--------------------------

Description

Apply a mapping to a vector directly. The mapping is temporary and not saved.

Usage

```
remap(x, ...)
```

Arguments

x	The values to apply the mapping to.
...	Passed to mapping().

Value

The values returned by calling the mapping function.

Examples

```
x <- c("A", "B", "A")  
remap(x, c(A=0, B=1))
```

text2mapping*Convenient shorthand for specifying mappings with text strings*

Description

Convenient shorthand for specifying mappings with text strings

Usage

```
text2mapping(  
  text,  
  file = NULL,  
  sep = "|",  
  flip = FALSE,  
  convert.na = TRUE,  
  numericWherePossible = TRUE,  
  ...  
)
```

Arguments

text	A multi-line string specifying a mapping with 2 columns (see examples).
file	If text is missing, read from this file instead.
sep	Character used as column separator.
flip	If TRUE, flip the column order to To, From (default FALSE).
convert.na	If TRUE, the string "NA" will be converted to NA.
numericWherePossible	If TRUE, the mapping will return a numeric vector if the codomain contains only numbers.
...	Further arguments passed to <code>mapping()</code> .

Value

A `mapping`.

Examples

```
f <- text2mapping("  
L | Low  
M | Medium  
H | High  
")  
f(warpbreaks$tension)
```
